Abstract. The paper presents a stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in gas transportation systems with multilinear linear sections of pipeline and a lot of craft compressor stations. A method for calculating the statistical properties of the dependent variables of the model from the statistical properties of the independent variables.

Key words: gas transportation systems, quasi-stationary non-isothermal mode, natural gas, statistical properties.

INTRODUCTION

At present, considerable experience has been gained in mathematical modeling and optimization of transport and distribution modes of natural gas in gas transportation systems (GTS) [1, 2, 3]. However, the optimal solutions obtained with their help correspond to absolutely accurate values of all parameters of mathematical models of technological equipment GTS and absolutely exact, the values of the boundary conditions and are, as a rule, on the boundary of the admissible region. In practice, this leads to the fact that even minor variations in the parameters of models or boundary conditions lead not only to a significant change in the optimal solution, but also to its derivation from the permissible region. Naturally, such "optimal" solutions are unacceptable in the operational dispatch management of the operating modes of the GTS.

In this article we give a general stochastic model of quasi-stationary non-isothermal mode of transport and distribution of natural gas in the GTS with multithread linear sections (MLS) and multistation compressor stations (CS). This model explicitly takes into account both the internal uncertainty of the technological elements parameters of the GTS, and external uncertainty parameters of the natural gas consumption processes by various categories of consumers. We consider the method of constructing the equivalent deterministic of stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in the GTS and the approximate solutions obtained by system of nonlinear and linear algebraic equations defined on a graph reflecting the structure of the GTS; and the method for calculating the statistical properties of the model's dependent variables from the statistical properties of the independent variables.

THE ANALYSIS OF RECENT RESEARCHES AND PUBLICATIONS

Fundamental studies of models and methods for calculating the pipeline systems operation modes are presented in [1, 2, 3]. In recent years, a large number of articles are devoted to the actual problem of stochastic modeling of pipeline systems operation modes [4-8]. The second pressing problem that considered in the articles is the problem of pipeline systems optimal control [9-15].

Solution of the problem of analysis and optimization the actual of gas transportation systems (GTS) operation modes is associated with the development of mathematical models that more adequately and in a wider range describe the actual modes in the GTS. One such model is a quasi-stationary non-isothermal mode of transport and distribution of natural gas in gas transportation systems with multithread linear sections (MLS), and many craft compressor stations (CS) [16-21].

MATHEMATICAL MODELING OF STOCHASTIC QUASI-STATIONARY MODE OF NATURAL GAS TRANSPORTATION IN GTS

To build a general stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in the GTS with MLS and many CS will use the results obtained in [1]: stochastic models of the quasi-stationary mode of transport of natural gas pipeline and the stochastic model mode gas-pumping unit (GPU). As a model of the structure of the GTS will use oriented connected graph \( G(V, E) \) [2], which is supplemented by a zero vertex and dummy arcs connecting this vertex with all inputs and outputs of the GTS, where: \( V (|V| = m) \) - a set of vertices, \( E \) - the set of arcs (\( |E| = n \)). Choose a tree graph \( G(V, E) \) so that its branches have become real and fake parts of the arc corresponding to the input of GTS. Then the set of arcs of the graph \( E \) represented as a union of disjoint subsets of the following: the real sections \( M \); fictitious sections on the network inputs \( L \); fictitious sections on the network output \( K \), fictitious sections, connecting the input of the active elements with the zero point (fictitious additional network input) \( T \); real tree branches \( M_1 \); real tree branches, which correspond to passive \( M_{11} \) and active \( M_{12} \) elements; real chords of the graph \( M_2 \); real chords
of the graph which correspond to passive $M_{11}$ and active $M_{22}$ elements; fictitious branches of a tree, which correspond to inputs $L_4$; branches of a tree on the inputs of the network with a preset flow $L_{11}$, pressure $L_{21}$ and temperature $L_{31}$; chords of the graph, which correspond to inputs $L_5$; chords of the graph of the network inputs with the preset flow $L_{12}$, pressure $L_{22}$, temperature $L_{32}$; fictitious chords which correspond to outputs $K_2 (K_2 = K)$; fictitious chords on the outputs of the network with a preset flow $K_{21}$ pressure $K_{22}$, temperature $K_{23}$; fictitious chords of the graph, corresponding to fictitious additional network input (arcs connecting the input of the active elements with the zero point) with a preset flow $T_{21}$. The quantity is considered

prestress if it is a normally distributed random variable with known expectation and variance.

We introduce the following notation: the number of nodes, in which pressure is preset $n_1 = |L_{11} \cup L_{21} \cup K_{12} \cup K_{22}|$, number of branches, in which flow is preset $n_1 = |L_{12} \cup L_{22} \cup K_{11} \cup K_{21}|$, the number of nodes, in which temperature is preset $n_1 -$ the number of branches with active elements $n_1 = |M_{11} \cup M_{22}|$.

Given quantities are random variables with normal distribution law and represented by their mathematical expectations and variances.

Then the stochastic model of quasi-stationary non-isothermal mode of transport and distribution of natural gas in the GTS can be represented as the following expressions:

\[
f_r = M_{21} \left[ \beta_r (\omega) q_r (\omega) + \sum_{i \in M_{i1}} b_{ir} \beta_i (\omega) q_i^2 (\omega) + \sum_{i \in M_{i1}} b_{ir} \tilde{c}_i (\omega) \left( q_i (\omega) - \frac{\tilde{b}_i (\omega) P_i (\omega)}{2c_i (\omega)} \right)^2 \right] = 0, \quad r \in M_{21},
\]

\[
f_r = M_{22} \left[ \tilde{c}_r (\omega) \left( q_r (\omega) - \frac{\tilde{b}_r (\omega) P_r (\omega)}{2c_r (\omega)} \right)^2 - \left( a_r (\omega) + \frac{\tilde{b}_r (\omega)}{4c_r (\omega)} \right) \right] = 0, \quad r \in M_{22},
\]

\[
f_r = M_{11} \left[ -P_{r1} (\omega) - \sum_{i \in L_{11}} b_{ir} P_{i1} (\omega) - \sum_{i \in L_{11}} b_{ir} P_r (\omega) + \sum_{i \in M_{i1}} b_{ir} \beta_i (\omega) q_i^2 (\omega) + \sum_{i \in M_{i1}} b_{ir} \tilde{c}_i (\omega) \left( q_i (\omega) - \frac{\tilde{b}_i (\omega) P_i (\omega)}{2c_i (\omega)} \right)^2 - \left( a_r (\omega) + \frac{\tilde{b}_r (\omega)}{4c_r (\omega)} \right) \right] = 0, \quad r \in L_{11},
\]

\[
f_r = M_{12} \left[ -P_{r2} (\omega) - \sum_{i \in L_{12}} b_{ir} P_{i2} (\omega) - \sum_{i \in L_{12}} b_{ir} P_r (\omega) + \sum_{i \in M_{i1}} b_{ir} \beta_i (\omega) q_i^2 (\omega) + \sum_{i \in M_{i1}} b_{ir} \tilde{c}_i (\omega) \left( q_i (\omega) - \frac{\tilde{b}_i (\omega) P_i (\omega)}{2c_i (\omega)} \right)^2 - \left( a_r (\omega) + \frac{\tilde{b}_r (\omega)}{4c_r (\omega)} \right) \right] = 0, \quad r \in L_{21},
\]

\[
f_r = M_{21} \left[ P_{r1} (\omega) - \sum_{i \in M_{i1}} b_{ir} P_{i1} (\omega) - \sum_{i \in M_{i1}} b_{ir} P_r (\omega) + \sum_{i \in M_{i1}} b_{ir} \beta_i (\omega) q_i^2 (\omega) + \sum_{i \in M_{i1}} b_{ir} \tilde{c}_i (\omega) \left( q_i (\omega) - \frac{\tilde{b}_i (\omega) P_i (\omega)}{2c_i (\omega)} \right)^2 - \left( a_r (\omega) + \frac{\tilde{b}_r (\omega)}{4c_r (\omega)} \right) \right] = 0, \quad r \in K_{21},
\]

\[
f_r = M_{22} \left[ P_{r2} (\omega) - \sum_{i \in M_{i1}} b_{ir} P_{i2} (\omega) - \sum_{i \in M_{i1}} b_{ir} P_r (\omega) + \sum_{i \in M_{i1}} b_{ir} \beta_i (\omega) q_i^2 (\omega) + \sum_{i \in M_{i1}} b_{ir} \tilde{c}_i (\omega) \left( q_i (\omega) - \frac{\tilde{b}_i (\omega) P_i (\omega)}{2c_i (\omega)} \right)^2 - \left( a_r (\omega) + \frac{\tilde{b}_r (\omega)}{4c_r (\omega)} \right) \right] = 0, \quad r \in K_{22},
\]
\[
f_r = M \left\{ -P_r(\omega)^2 - \sum_{i=1}^{n} b_{r,i} P^2_r(\omega) - \sum_{i=1}^{n} b_{r,i} P^2_r(\omega) + \sum_{i=1}^{n} \beta_i(\omega) q_i^2(\omega) + \sum_{i=1}^{n} b_{r,i} q_i(\omega) \left( \frac{\dot{b}_r(\omega) P_r(\omega)}{2 c_r(\omega)} \right)^2 - \left( a_i(\omega) + \frac{\dot{b}_r^2(\omega)}{4 c_r(\omega)} \right) P^2_r(\omega) \right\} = 0, \quad r \in T_{2i},
\]

\[
f_r = M \left\{ \sum_{i=1}^{n} b_{r,i} q_i(\omega) + \sum_{i=1}^{n} b_{r,i} q_i^2(\omega) - q_i^2(\omega) \right\} = 0,
\]

\[
f_r = M \left\{ T_r(\omega) - T_{r'} + \left( T_{r'} - T_{r''} \right) e^{-\theta_r(\omega) L} \right\} = 0, \quad r \in M_{11} \cup M_{21},
\]

\[
f_r = M \left\{ T_r(\omega) - T_{r'} \left( P_r(\omega) / P_{r'}(\omega) \right)^{\frac{\theta_r(\omega)-1}{\theta_{r'}(\omega)}} \right\} = 0, \quad r \in M_{12} \cup M_{22},
\]

\[
f_r = M \left\{ T_r(\omega) \sum_q q_i(\omega) - \sum_q q_i(\omega) T_{r'}(\omega) \right\} = 0, \quad r \in V,
\]

\[
f_r = M \left\{ T_r(\omega) - T_{r'} + \left[ T_r(\omega) - T_{r'} \right] / \theta_r(\omega) L \right\} \left( 1 - e^{-\theta_r(\omega) L} \right) = 0, \quad r \in M_{11} \cup M_{21},
\]

\[
f_r = M \left\{ P_r^2(\omega) - P_{r'}^2(\omega) - \beta_i(\omega) q_i^2(\omega) \right\} = 0, \quad r \in M_{11} \cup M_{21},
\]

\[
f_r = M \left\{ \tilde{a}_i(\omega) P_r^2(\omega) - \tilde{b}_r(\omega) P_r(\omega) q_i(\omega) - \tilde{c}_i(\omega) q_i^2(\omega) \right\} = 0, \quad r \in M_{12} \cup M_{22},
\]

where: \( P^2_r, P_r, T_r, q_r, q_i^2 \) – marks the preset quantities;
\( a_i, c_i \) – the set of elements on which the gas comes into the \( j \)-th node, and is bled from it, respectively;
\( b_{r,i} \) – cyclomatic matrix element, located at the intersection of the \( r \)-th row and the \( i \)-th column;
\( P_r(\omega), P_{r'}(\omega) \) – random variables, characterizing the pressure at the beginning and the end of the \( i \)-th arc;
\( T_r(\omega), T_{r'}(\omega) \) – random variables, characterizing the temperature at the beginning and the end of the \( i \)-th arc;
\( q_i(\omega) \) – random variable characterizing the commercial flow of the \( i \)-th arc;
\( \beta_i(\omega) \) – random variable characterizing the assessment ratio of hydraulic resistance of pipeline [22]:

\[
\beta_i(\omega) = \frac{\Delta(\omega) L T_{r}(\omega) Z_{r}(\omega)}{\tau_i a_i^2 \phi_i^2 E_i(\omega) D_i^2},
\]

\( \Delta(\omega) \) – random variable characterizing the assessment ratio of the relative density of natural gas in the air, \( T_{r}(\omega), Z_{r}(\omega) \) – random variable characterizing the estimation of the average temperature and average density of natural gas of \( i \)-th arc, \( E_i(\omega) \) – random variable characterizing the assessment of effectiveness ratio \( i \)-th pipeline;
\( \theta_r(\omega) \) – random variable defined by the expression [22]:

\[
\theta_r(\omega) = 62.6 K_r(\omega) D_R / 10^6 q_r(\omega) \Delta(\omega) B(\omega),
\]

\( K_r(\omega) \) – random variable characterizing the estimate of the average values of the coefficient of heat transfer from the gas in the ground on the \( i \)-th section of the pipeline, \( B(\omega) \) – a random variable characterizing the estimate of the coefficient of the specific heat of natural gas;
\( a_i(\omega), \tilde{b}_r(\omega), \tilde{c}_i(\omega) \) – random variable characterizing the approximation estimates for the coefficients describing the degree of compression of GPU from the commercial flow for GPU-owned \( i \)-th arc:
$a_{ii}(\omega), b_{ii}(\omega), c_{ii}(\omega)$ and $d_{ii}(\omega), e_{ii}(\omega), f_{ii}(\omega)$ – random variables characterizing the estimates of coefficients of approximation polynomials of the compression degree

GPA first and second degree, respectively, at $n_i = n_0, j = 1, \ldots, n'$, \( n_i'(\omega) \) – random variables characterizing the above assessment of the relative speed drive of \( i \)-th GPA:

$$n_i'(\omega) = \left( \frac{n_i}{n_0} \right)_{ii} = \frac{n_i}{n_0} \sqrt{\frac{Z_{ii}(\omega) R_{ii}(\omega)}{Z_{ii}(\omega) R_{ii}(\omega)}}.$$

$$\mu_i'(\omega) = \frac{\mu_i(\omega)}{\mu(\omega)} - 1 = \eta_{pol}(\omega) \frac{k_i}{k-i}, \quad (20)$$

where: \( \eta_{pol}(\omega) \) – random variable characterizing the assessment polytropic efficiency in form of the following expression:

$$\eta_{pol}(\omega) = d_{ii}(\omega) + d_{ii}(\omega) Q_{dii}(\omega) + d_{ii}(\omega) Q_{dii}(\omega), \quad (21)$$

$$Q_{dii}(\omega) \) – random variable characterizing the performance evaluation of the reduced volume of \( i \)-th GPA by expression:

$$Q_{dii}(\omega) = \frac{n_i}{n_0} \frac{Z(\omega) R_{ii}(\omega)}{1440} \frac{q_{ii}(\omega)}{P_{ii}(\omega)}.$$

The stochastic model of quasi-stationary non-isothermal mode of transport and distribution of natural gas in GTS (1)–(14) takes into account almost all sources of internal and external uncertainties operation modes and allows enough to adequately analyze and simulate a wide class of quasi-stationary modes of the GTS. Of great interest, this model is to optimize the planned modes GTS. In this case the optimal plan of GTS at a given time interval is represented as mathematical expectations and variances of parameters of flows of natural gas (pressure, flow, temperature) on the inputs and outputs of the GTS, expectations and variances of operational parameters (speed drives) GPU. To calculate the mathematical expectation of flow parameters of natural gas for each real portion, and at every entrance and exit of the GTS is necessary to construct a deterministic equivalent stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in GTS (1)–(14).

**DEVELOPMENT OF THE STOCHASTIC MODEL FOR NATURAL GAS TRANSPORTATION AND DISTRIBUTION IN GTS**

To build a deterministic equivalent stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in GTS it is necessary to replace all the random quantities in the system of equations (1)–(14) by their assessments in the form of conditional expectations. Because of the nonlinearity of the system of equations (1)–(14), such replacement will result in the right side of these equations will take the form of non-zero residuals, the sign and magnitude of which, according to Jensen's inequality [3, 16], will determine by the degree of convexity (concavity) of implicit functions from the variables defining the system of equations (1)–(14). As shown by our studies, the numerical value of these residuals is comparable with the magnitude of error in the numerical solution of equations (1)–(14). Therefore, without loss of generality, by residuals of the deterministic equivalent stochastic model of a quasi-stationary non-isothermal mode of transportation and distribution of natural gas in (1)–(14) may be neglected.

In work [3] was shown that in this case the deterministic equivalent stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas in the transmission system (1)–(14) will coincide with the steady-state model of the flow of gas pipeline networks with active elements, in which the boundary conditions and unknown parameters are represented by their conditional expectations. A numerical algorithm for solving systems of equations of the deterministic equivalent stochastic model of a quasi-stationary non-isothermal mode of transport and distribution of natural gas transportation systems also is given in [3].

The formulas given below are a deterministic analog of equations (1)–(14):

$$f_r = \overline{P}_r q_r^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i - \frac{\pi}{a_r + \frac{b_r}{4c_i} - 1} \overline{P}_r^2 = 0, r \in M_{21},$$

$$f_r = \overline{p}_r q_r^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i - \frac{\pi}{a_r + \frac{b_r}{4c_i} - 1} \overline{P}_r^2 = 0, r \in M_{22},$$

$$f_r = -\overline{P}_r - \sum_{i=0}^{n_r} b_{rr} \overline{P}_r^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i - \frac{\pi}{a_r + \frac{b_r}{4c_i} - 1} \overline{P}_r^2 = 0, r \in L_{21},$$

$$f_r = -\overline{P}_r^2 - \sum_{i=0}^{n_r} b_{rr} \overline{P}_r^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i^2 + \sum_{i=0}^{n_r} b_{rr} \overline{P}_r q_i - \frac{\pi}{a_r + \frac{b_r}{4c_i} - 1} \overline{P}_r^2 = 0, r \in L_{22},$$
where the parameters marked feature of the above are estimates in the form of mathematical expectation of the random variables model presented in next section.

**ASSESSING THE RELATIONSHIP OF STATISTICAL PROPERTIES OF THE DEPENDENT AND THE INDEPENDENT VARIABLES IN THE STOCHASTIC MODEL**

Formal statement of the problem of assessing the statistical properties of the dependent variables in the stochastic model of the quasi-stationary non-isothermal natural gas transportation mode in the GTS, is the necessity to determine the numerical characteristics of random variables, which are the solution of the deterministic analogue of the functional relationships (1)–(14) supplemented by equations (15)–(22):

\[
\begin{align*}
f_r &= \frac{\bar{P}_m^2}{\sigma_{\bar{P}_m}} - \sum_{i=1}^{n} b_{i\alpha} \bar{P}_m^2 + \sum_{i=1}^{n} b_{i\beta} \bar{P}_m^2 + \sum_{i=1}^{n} b_{i\gamma} \bar{P}_m^2 + \sum_{i=1}^{n} b_{i\delta} \bar{P}_m^2 + \sum_{i=1}^{n} b_{i\epsilon} \bar{P}_m^2 + \sum_{i=1}^{n} b_{i\zeta} \bar{P}_m^2 = 0, \\
f_r &= \bar{T}_m - T_{gr} - \left(\bar{T}_m - T_{gr}\right)e^{-\beta T_{gr}}, \\
f_r &= \bar{T}_m - T_{gr} - \left(\bar{T}_m - T_{gr}\right)e^{-\gamma T_{gr}}, \\
f_r &= \bar{T}_m - T_{gr} - \left(\bar{T}_m - T_{gr}\right)e^{-\alpha T_{gr}}, \\
f_r &= \bar{T}_m - T_{gr} - \left(\bar{T}_m - T_{gr}\right)e^{-\beta T_{gr}}.
\end{align*}
\]

Then the solution takes on the following form:

\[
\begin{align*}
\bar{X} = (P_1, P_2, ..., P_m, q_1, q_2, ..., q_n, T_1, T_2, ..., T_n, E, K_f) = (\bar{P}, \bar{q}, \bar{T}, E, K_f) \quad \text{(24)}
\end{align*}
\]

where: \(N\) – number of calculated parameters in the general case equal to \(N = (2n + 5m + 7g_1 + 4m_1 - nl - l)\), and \(N2 = (m1 + n1 + l1 + 2)\) – number of the preset parameters.

Since the system (24) is given implicitly, and the conditions of the theorem "on the existence and differentiability of the implicit functions determined by a system of functional equations" [17, 18] hold, we assume that there exists a functional dependence between random variables that are system's dependent and independent parameters, which is defined by the model (1)–(22).

As a result of applying the method of linearizing the function of several random variables [17, 18], as well as the subsequent applying the properties of the numerical characteristics of functions of random variables to the resulting expression, we obtain the following dependencies of the statistical characteristics (excluding random variables correlation):

\[
M_{x_i} = F_i(M_{p_1}, M_{p_2}, ..., M_{p_m}, M_{q_1}, M_{q_2}, ..., M_{q_n}, M_{T_1}, M_{T_2}, ..., M_{T_n}, E, M_{K_f}), \quad i = \overline{1, N}, \quad (25)
\]
\[ \sigma^2_{X_i} \approx \sum_{j=1}^{N} \left[ \frac{\partial X_i}{\partial q_j} \right]^2 \sigma^2_{q_j}, \]

\[ \sigma^2_{X_i} \approx \sum_{j=1}^{N} \left[ \frac{\partial X_i}{\partial E_j} \right]^2 \sigma^2_{E_j} + \sum_{j=1}^{N} \left[ \frac{\partial X_i}{\partial T_j} \right]^2 \sigma^2_{T_j} + \sum_{j=1}^{N} \left[ \frac{\partial X_i}{\partial K_{ij}} \right]^2 \sigma^2_{K_{ij}} \right] \eta_i, \quad i=1, N. \] (26)

where the parameters marked feature of the above are estimates in the form of mathematical expectation of the random variables model presented in next section.

To determine the values of the expectations (25) we need to solve the system of equations (23), relative to the variables – the random varieties

\[ \bar{F}, \bar{T}, \bar{q}, \bar{T}_{op}, \beta, \bar{a}, \bar{b}, \bar{c}, \bar{a}_2, \bar{b}_2, \bar{c}_2, \bar{n}, \bar{\eta}, \bar{\mu}, \bar{Q}_{op} \]
at the point, corresponding to the expectations of gas flow parameters in the network.

To find the variance (26) it is necessary to calculate the partial derivatives used in dependencies. Since the system (24) is implicit, and therefore it is impossible to find its general analytical solution, a method for calculating the partial derivatives for a system of implicitly defined functions follows.

THE METHOD OF CALCULATING THE PARTIAL DERIVATIVES OF IMPLICITLY DEFINED FUNCTIONS

Since for the system of implicitly defined functions being considered (24), at points, which correspond to optimal and average values of the network parameters, the conditions of the theorem "On the existence and differentiability of the implicit functions determined by a system of functional equations" hold, then the partial derivatives \( \frac{\partial F}{\partial Y_j} \), \( i=1, N, j=1, N^2 \) can be found, according to the general form of the partial derivative of implicitly defined function:

\[ f_r = M_{\omega} \left\{ \beta_r(\omega) - \frac{\Delta(\omega)LT_r(\omega)\cdot Z_r(\omega)}{\tau_r(\omega)\cdot E_r(\omega)D_r^{1/2}} \right\} = 0, \quad r \in M_{11} \cup M_{21} \] (29)

\[ f_r = M_{\omega} \left\{ \theta_r(\omega) - \frac{62.6K_r(\omega)D_{12}}{10^3q_r(\omega)\Delta(\omega)B_r(\omega)} \right\} = 0, \quad r \in M_{11} \cup M_{21} \] (30)

\[ f_r = M_{\omega} \left\{ a_{r2}(\omega) - n_{r2}(\omega)\cdot a_{r2}(\omega) - n_{r2}(\omega)\left(1-n_{r2}(\omega)\right)a_{r2}(\omega) - \left(1-n_{r2}(\omega)\right) \right\} = 0, \] (31)

\[ f_r = M_{\omega} \left\{ b_{r2}(\omega) - n_{r2}(\omega)\cdot b_{r2}(\omega) - n_{r2}(\omega)\left(1-n_{r2}(\omega)\right)b_{r2}(\omega) \right\} = 0, \] (32)

\[ f_r = M_{\omega} \left\{ c_{r2}(\omega) - n_{r2}(\omega)\cdot c_{r2}(\omega) - n_{r2}(\omega)\left(1-n_{r2}(\omega)\right)c_{r2}(\omega) \right\} = 0, \] (33)

\[ f_r = M_{\omega} \left\{ a_r(\omega) - a_r(\omega) \right\} = 0. \] (34)

Let's denote a couple more classes of functions, as the dependences (15) – (22) are included in the system (23) in exactly that form.
THE STOCHASTIC MODEL OF QUASI-STATIONARY NON-ISOTHERMAL MODE ...

\[
f_r = M_\omega \left[ b_r(\omega) - b_s(\omega) \left( \frac{n}{n_0} \gamma_0 Z(\omega) RT_r(\omega) \right) \right] = 0, \quad (35)
\]

\[
f_r = M_\omega \left[ c_r(\omega) - c_s(\omega) \left( \frac{n}{n_0} \gamma_0 Z(\omega) RT_r(\omega) \right)^k \right] = 0, \quad (36)
\]

\[
f_r = M_\omega \left[ n_r(\omega) - \frac{n}{n_0} \sqrt{Z_r(\omega) R_r T_r(\omega)} \right] = 0, \quad (37)
\]

\[
f_r = M_\omega \left[ \mu_r(\omega) - \eta_{\text{pol}, r}(\omega) \right] = 0, \quad (38)
\]

\[
f_r = M_\omega \left[ Q_{r,\omega}(\omega) - \frac{n}{n_0} \gamma_0 Z(\omega) RT_r(\omega) \right] = 0. \quad (40)
\]

For all expressions (31) – (40) \( r \in M_{12} \cup M_{22} \).

Analytical form of partial derivatives \( \frac{\partial f_r}{\partial X_k} \) and \( \frac{\partial f_r}{\partial Y_j} \) (\( i, k = 1, N_i \) and \( j = 1, N_j \)) is presented below [21]:

Partial derivatives \( \frac{\partial f_r}{\partial q_r} \) take on the form:

\[
\frac{\partial f_r}{\partial q_r} = 2c_r \left[ q_r + 2 \sum_{i=1}^{N_i} b_i R_i c_i q_r \right] + 2 \sum_{i=1}^{N_i} b_i R_i c_i q_r - \frac{b_r}{2c_r} P_r.
\]

\[
\frac{\partial f_r}{\partial q_r} = 2c_r \left[ q_r - \frac{b_r}{2c_r} P_r \right] + 2 \sum_{i=1}^{N_i} b_i R_i c_i q_r - \frac{b_r}{2c_r} P_r.
\]

Partial derivatives \( \frac{\partial f_r}{\partial \beta_r} \) equal:

\[
\frac{\partial f_r}{\partial \beta_r} = q_r(\omega)^2.
\]

Partial derivatives \( \frac{\partial f_r}{\partial \beta_{l\neq r}} \) equal:

\[
\frac{\partial f_r}{\partial \beta_{l\neq r}} = -q_r(\omega)^2.
\]

Partial derivatives \( \frac{\partial f_r}{\partial \beta_{l\neq r}} \) equal:

\[
\frac{\partial f_r}{\partial \beta_{l\neq r}} = 1.
\]

Partial derivatives \( \frac{\partial f_r}{\partial P_r} \) (\( r \neq l \)) equal:

\[
\frac{\partial f_r}{\partial P_r} = -2 \sum_{i=1}^{N_i} b_i R_i c_i q_r \left[ \frac{b_r}{2c_r} P_r - \frac{b_r}{2c_r} P_r + \left( a_r + \frac{b_r^2}{4c_r} \right) P_r \right].
\]

Partial derivatives \( \frac{\partial f_r}{\partial q_l} \) (\( l \neq r \)) equal:

\[
\frac{\partial f_r}{\partial q_l} = 2 \sum_{i=1}^{N_i} b_i R_i c_i q_l + 2 \sum_{i=1}^{N_i} b_i R_i c_i q_l - \frac{b_l}{2c_l} P_l.
\]

\[
\frac{\partial f_r}{\partial q_l} = -2 d_{l,r} \left[ \frac{b_r}{2c_r} q_l - \frac{b_r}{2c_r} P_r + \left( a_r + \frac{b_r^2}{4c_r} \right) P_r \right].
\]

where: \( r \in M_{22}, l \in T_{21} \).
\[
d_{li} = \begin{cases} 1, & \text{if the end of arch } li \text{ is the beginning of arch } i \text{,} \\ 0, & \text{otherwise} \end{cases}
\]

\[
\frac{\partial f_r}{\partial P_{r|k}} = -2b_{il}|P_{n|k}|, \quad r \in L_{22} \cup K_{22} \cup T_{21}, \quad l \in L_{11}.
\]

Partial derivatives \( \frac{\partial f_r}{\partial P_{r|k}} \) equal:

\[
\frac{\partial f_r}{\partial P_{r|k}} = -2P_{r|k}(\omega), \quad \frac{\partial f_r}{\partial P_{r|k}} = -2P_{r|k}(\omega).
\]

Partial derivatives \( \frac{\partial f_r}{\partial P_{r|k}} \) equal:

\[
\frac{\partial f_r}{\partial P_{r|k}} = \frac{1}{\mu_r} T_r(\omega) \left( P_{r|k} \right)^{\frac{1}{2}} \left( \frac{1}{P_{r|k}} \right)^{\frac{1}{2}}, \\
\frac{\partial f_r}{\partial P_{r|k}} = 2P_{r|k}(\omega), \\
\frac{\partial f_r}{\partial P_{r|k}} = 2\alpha_iP_{r|k}(\omega), \\
\frac{\partial f_r}{\partial P_{r|k}} = \frac{n_0}{n} \frac{Z(\omega)RT_{r|k}(\omega)q_i(\omega)}{1440} P_r(\omega).
\]

Partial derivatives \( \frac{\partial f_r}{\partial T_r} \) equal:

\[
\frac{\partial f_r}{\partial T_r} = e^{-\theta_r(\omega)L}, \\
\frac{\partial f_r}{\partial T_r} = -\frac{P_{r|k}}{P_{r|k}}, \\
\frac{\partial f_r}{\partial T_r} = \frac{1-e^{-\theta_r(\omega)L}}{\theta_r(\omega)L}, \\
\frac{\partial f_r}{\partial T_r} = -b_{2i}(\omega) \frac{n_0 Z(\omega)R}{n_0} 1440, \\
\frac{\partial f_r}{\partial T_r} = -2c_{2i}(\omega) T_r(\omega) \left( \frac{n_0 Z(\omega)R}{n_0} \right)^2 1440.
\]
THE STOCHASTIC MODEL OF QUASI-STATIONARY NON-ISOTHERMAL MODE ...

\[ \frac{\partial f_r}{\partial b_i} = \sum_{i \in M_{i1}} b_{i}^2 d_i \begin{bmatrix} -P_{i1}(\omega) \left( q_i(\omega) - \frac{b_i(\omega)P_{i1}(\omega)}{2c_i(\omega)} \right) - \frac{b_i(\omega)P_{i1}(\omega)}{2c_i(\omega)} \end{bmatrix} \]

\[ r \in M_{21} \cup L_2 \cup K_2 \cup T_{21}; \quad \omega \in M_{21} \cup L_2 \cup K_2 \cup T_{21}. \]

\[ \frac{\partial f_r}{\partial c_i} = \sum_{i \in M_{i2}} b_{i}^2 d_i \begin{bmatrix} \left( q_i(\omega) - \frac{b_i(\omega)P_{i1}(\omega)}{2c_i(\omega)} \right)^2 + \frac{b_i(\omega)P_{i1}(\omega)^2}{4c_i(\omega)} + \sum_{i \in M_{i2}} b_{i}^2 d_i \left( \frac{b_i(\omega)P_{i1}(\omega)^2}{2c_i(\omega)} + \frac{b_i(\omega)P_{i1}(\omega)^2}{4c_i(\omega)} \right) \end{bmatrix} \]

\[ r \in M_{22}, \quad \omega \in T_{21}. \]

Partial derivatives \( \frac{\partial f_r}{\partial c_i} \) equal:

\[ \frac{\partial f_r}{\partial a_i} = P_{i1}(\omega), \quad \frac{\partial f_r}{\partial b_i} = 1, \quad \frac{\partial f_r}{\partial c_i} = 1. \]

Partial derivatives \( \frac{\partial f_r}{\partial b_i} \) equal:

\[ \frac{\partial f_r}{\partial b_i} = P_{i1}(\omega)q_i(\omega), \quad \frac{\partial f_r}{\partial b_i} = 1. \]

Partial derivatives \( \frac{\partial f_r}{\partial c_i} \) equal:

\[ \frac{\partial f_r}{\partial c_i} = q_i^2(\omega), \quad \frac{\partial f_r}{\partial c_i} = 1. \]
The rest partial derivatives for next equations:
\[
\frac{\partial f_i}{\partial a_{2r}} = 1, \quad \frac{\partial f_i}{\partial a_{1r}} = -n_i^2(\omega), \\
\frac{\partial f_i}{\partial b_{2r}} = -2n_i^2(\omega)\left(1 - n_i^2(\omega)\right).
\]

The rest partial derivatives for next equations:
\[
\frac{\partial f_i}{\partial b_{2r}} = 1, \quad \frac{\partial f_i}{\partial b_{1r}} = -n_i^4(\omega), \\
\frac{\partial f_i}{\partial c_{2r}} = -2n_i^2(\omega)\left(1 - n_i^2(\omega)\right).
\]

The rest partial derivatives for next equations:
\[
\frac{\partial f_i}{\partial c_{2r}} = 1, \quad \frac{\partial f_i}{\partial c_{1r}} = -n_i^4(\omega), \\
\frac{\partial f_i}{\partial c_{0r}} = -2n_i^2(\omega)\left(1 - n_i^2(\omega)\right).
\]

And partial derivatives \( \frac{\partial f_i}{\partial a_{2r}}, \frac{\partial f_i}{\partial b_{2r}}, \frac{\partial f_i}{\partial c_{2r}} \) respectively equal:
\[
\frac{\partial f_i}{\partial a_{2r}} = -1, \\
\frac{\partial f_i}{\partial b_{2r}} = \frac{n}{n_0} \gamma_0 Z(\omega) RT_e(\omega) \frac{1}{1440}, \\
\frac{\partial f_i}{\partial c_{2r}} = -\left(\frac{n}{n_0} \gamma_0 Z(\omega) RT_e(\omega)\right)^2.
\]

Partial derivatives \( \frac{\partial f_i}{\partial \mu_r} \) equal:
\[
\frac{\partial f_i}{\partial \mu_r} = -\frac{1}{\mu^2} T_w(\omega) (e_r) \left(\frac{1}{\nu_r} \right) \operatorname{Ln} \epsilon_r, \quad \frac{\partial f_i}{\partial \mu_r} = 1.
\]

Partial derivatives \( \frac{\partial f_i}{\partial \eta_r} \) equal:
\[
\frac{\partial f_i}{\partial \eta_r} = \frac{k}{k - 1}, \quad \frac{\partial f_i}{\partial \eta_{polr}} = 1.
\]

The rest partial derivatives for equation equal:
\[
\frac{\partial f_i}{\partial d_{0r}} = -1, \quad \frac{\partial f_i}{\partial d_{1r}} = -Q_3^2(\omega), \quad \frac{\partial f_i}{\partial d_{2r}} = -Q_3^2(\omega), \\
\frac{\partial f_i}{\partial d_{3r}} = -Q_3^2(\omega).
\]

The rest partial derivatives \( \frac{\partial f_i}{\partial X_k} = 0 \) and \( \frac{\partial f_i}{\partial Y_j} = 0. \)

**MODELING RESULTS**

Let us consider the following example. Well perform the hydraulic calculation for a section of the gas transport system in the form of a main gas pipeline, which includes compressor section with five gas pumping units. Figure 1 shows the corresponding computational graph, consisting of 16 nodes and 21 branches, 5 of which are active (arcs 14 \( \rightarrow \) 18). Length of pipes: \( L_2 = 102 \text{ km}, \) \( L_{20} = 34 \text{ km}, \) \( L_{3-19} = 0.3 \text{ km}, \) the diameters \( d_2 = d_{20} = 1.4 \text{ m}, \) \( d_{3-19} = 1.02 \text{ m}. \)

![Fig. 1: Graph of GTS fragment](image)

Suppose the maximum deviations of preset parameters are as follows:

- commercial flow – \( \sigma_q = q^* \delta_q, \) where \( \delta_q = 1\% \) – relative error in measuring commercial flow;
- for pressure – \( \sigma_p = P^* \delta_p, \) where \( \delta_p = 1\% \) – relative error of pressure measurements;
- for temperature – \( \sigma_T = T^* \delta_T, \) where \( \delta_T = 0.35\% \) – relative error of temperature measurements;
- for efficiency factor – \( \sigma_E = E^* \delta_E, \) where \( \delta_E = 0.35\% \) – relative error of measurements;
- for the average coefficient of the gas – \( \sigma_k = \kappa^* \delta_k, \) where \( \delta_k = 0.35\% \) – relative error of measurements.

As the mathematical expectations of random variables at the inputs the following parameters: \( M_{T1} = 313 \text{ K}, \) \( M_{P1} = 8.3 \text{ MПа}, \) \( M_{q21} = 102 \text{ млн м}^3/\text{день}, \) were taken.

Next, we determined \( \sigma_{q21} = 1.02 \text{ млн м}^3/\text{день}, \) \( \sigma_{P1} = 0.083 \text{ MПа}, \) \( \sigma_{T1} = 1.0955 \text{ K}, \) as a result of the calculations the expectations (13)–(16), were obtained, among which the study of random variables \( T_{16}, P_{16}, q_1 \) is of a special interest. That is, the calculated parameters for nodes 1 and 16 in Fig. 1: \( M_{T16} = 283.425 \text{ K}, \) \( M_{P16} = 6.07 \text{ MПа}, \) \( M_{q1} = 102 \text{ млн м}^3/\text{день}. \)
To establish the dependence between the variances of random variables $T_{16}, P_{16}, q_{1}$ and variances $T_{1}, P_{1}, q_{21}$ of parameters we used the method presented in Section 3. Below are the charts of some of them—each such chart shows two dependencies: in the first case partial derivatives were calculated analytically (dashed line), as described in Section 4, while in the second case—numerically (solid line).

**Fig. 2.** Dependence between the variances of output pressure $P_{16}$ and variances input pressure $P_{1}$

**Fig. 3.** Dependence between the variances of output pressure $P_{16}$ and variances input temperature $T_{1}$

**Fig. 4.** Dependence between the variances of output pressure $P_{16}$ and variances output commercial flow $q_{21}$

**Fig. 5.** Dependence between the variances of output temperature $T_{16}$ and variances input pressure $P_{1}$

**Fig. 6.** Dependence between the variances of output temperature $T_{16}$ and variances input temperature $T_{1}$

**Fig. 7.** Dependence between the variances of output temperature $T_{16}$ and variances input pressure $q_{21}$
CONCLUSIONS

1. This paper addresses the problem of mathematical modeling of stationary non-isothermal modes of the natural gas transportation with the multithread LS and multishop CS. The novelty of this work lies in the fact that for the first time the problem of mathematical modeling of stochastic quasi-stationary non-isothermal mode of natural gas transportation over the network with multithread LS and multishop CS, and the problem of assessing the relation between the statistical properties of the dependent and independent variables in presented model was solved.

2. Practical significance is that these models provide upper and lower bounds for ranges of gas flow parameters at any GTS node for a given level of external stochastic disturbances.
